

Funcons-beta: Value-Types

The P_{LAN}CompS Project

Funcons-beta/Values/Value-Types/Value-Types.cbs*

Value Types

```
[ Type values
  Alias vals
  Type value-types
  Alias types
  Type empty-type
  Funcon is-in-type
  Alias is
  Funcon is-value
  Alias is-val
  Funcon when-true
  Alias when
  Type cast-to-type
  Alias cast
  Type ground-values
  Alias ground-vals
  Funcon is-equal
  Alias is-eq ]
```

Values

```
Built-in Type values
Alias vals = values
```

The type `values` includes all values provided by CBS.

*Suggestions for improvement: plancomps@gmail.com.
Issues: <https://github.com/plancomps/CBS-beta/issues>.

Some funcons are declared as value constructors. Values are constructed by applying value constructor funcons to the required arguments.

Values are immutable and context-independent. Their structure can be inspected using patterns formed from value constructors and variables. Computations can be extracted from values and executed, but the structure of computations cannot be inspected.

Some types of values and their funcons are declared as built-in, and not further specified in CBS. New types of built-in values can be added to CBS by its developers.

New algebraic datatypes may be declared by users of CBS. Their values are disjoint from built-in values.

Meta-variables T, T_1, T_2 <: **values**

Types

Built-in Type **value-types**

Alias **types** = **value-types**

Built-in Type **empty-type**

A type T is a value that represents a set of values.

The values of type **types** are all the types, including **types** itself.

The formula $V : T$ holds when V is a value of type T , i.e., V is in the set represented by the type T .

The formula $T_1 <: T_2$ holds when T_1 is a subtype of T_2 , i.e., the set represented by T_1 is a subset of the set represented by T_2 .

The set of types forms a Boolean algebra with the following operations and constants: $* T_1 T_2$ (meet/intersection) $* T_1 | T_2$ (join/union) $* \sim T$ (complement) $* \mathbf{values}$ (top) $* \mathbf{empty-type}$ (bottom)

Subtyping: $T_1 <: T_2$ is the partial order defined by the algebra.

Subsumption: If $V : T_1$ and $T_1 <: T_2$ both hold, so does $V : T_2$.

Indivisibility: For each value V and type T , either $V : T$ or $V : \sim T$ holds.

Universality: $V : \mathbf{values}$ holds for all values V .

Emptiness: $V : \mathbf{empty-type}$ holds for no value V .

‘Type N’ declares the name ‘N’ to refer to a fresh value constructor and includes it as an element of **types**.

‘Type $N \sim > T$ ’ moreover specifies ‘Rule $N \sim > T$ ’, so that ‘ N ’ can be used as an abbreviation for the type term ‘ T ’.

‘Type $N <: T$ ’ declares the name ‘ N ’ to refer to a fresh value constructor in **types**, and asserts ‘ $N <: T$ ’.

Parametrised type declarations introduce generic (possibly dependent) types, i.e., families of individual types, indexed by types (and by other values). For example, **lists**(T) is parameterised by the type of list elements T . Replacing a parameter by $_$ denotes the union over all instances of that parameter, e.g., **lists**($_$) is the union of all types **lists**(T) with $T : \mathbf{types}$.

Qualified variables $V : T$ in terms range over values of type T . Qualified variables $T_1 <: T_2$ in terms range over subtypes T_1 of T_2 .

Funcon **is-in-type**($V : \mathbf{values}, T : \mathbf{types}$) : $\Rightarrow \mathbf{booleans}$
Alias **is** = **is-in-type**

is-in-type(V, T) tests whether $V : T$ holds. The value V need not be a ground value, but T should not require testing any computation types.

Rule
$$\frac{V : T}{\mathbf{is-in-type}(V : \mathbf{values}, T : \mathbf{types}) \rightsquigarrow \mathbf{true}}$$

Rule
$$\frac{V : \sim T}{\mathbf{is-in-type}(V : \mathbf{values}, T : \mathbf{types}) \rightsquigarrow \mathbf{false}}$$

Option types

For any value type T , the elements of the option type $(T)^\text{?}$ are the elements of T together with the empty sequence $()$, which represents the absence of a value. Option types are a special case of sequence types.

A funcon whose result type is an option type $(T)^\text{?}$ may compute a value of type T or the empty sequence $()$; the latter represents undefined results of partial operations.

The parentheses in $(T)^\text{?}$ and $()$ can be omitted when this does not give rise to grouping ambiguity. Note however that $T^\text{?}$ is a meta-variable ranging over option types, whereas $(T)^\text{?}$ is the option type for the value type T .

Funcon **is-value**($_ : \mathbf{values}^\text{?}$) : $\Rightarrow \mathbf{booleans}$
Alias **is-val** = **is-value**

is-value($V^\text{?}$) tests whether the optional value $V^\text{?}$ is a value or absent.

Rule $\text{is-value}(_ : \text{values}) \rightsquigarrow \text{true}$

Rule $\text{is-value}(_) \rightsquigarrow \text{false}$

Funcon $\text{when-true}(_ : \text{booleans}, _ : T) : \Rightarrow (T)?$

Alias $\text{when} = \text{when-true}$

$\text{when-true}(B, V)$ gives V when B is true , and $()$ when B is false .

Rule $\text{when-true}(\text{true}, V : \text{values}) \rightsquigarrow V$

Rule $\text{when-true}(\text{false}, V : \text{values}) \rightsquigarrow ()$

Funcon $\text{cast-to-type}(V : \text{values}, T : \text{types}) : \Rightarrow (T)?$

Alias $\text{cast} = \text{cast-to-type}$

$\text{cast-to-type}(V, T)$ gives V if it is in T , otherwise $()$.

Rule
$$\frac{V : T}{\text{cast-to-type}(V : \text{values}, T : \text{types}) \rightsquigarrow V}$$

Rule
$$\frac{V : \sim T}{\text{cast-to-type}(V : \text{values}, T : \text{types}) \rightsquigarrow ()}$$

Ground values

Built-in Type ground-values

Alias $\text{ground-vals} = \text{ground-values}$

The elements of ground-values are all values that are formed entirely from value-constructors, and thus do not involve computations.

A type is a subtype of ground-values if and only if all its elements are included in ground-values .

Funcon $\text{is-equal}(V : \text{values}, W : \text{values}) : \Rightarrow \text{booleans}$

Alias $\text{is-eq} = \text{is-equal}$

$\text{is-equal}(V, W)$ returns true when V and W are identical ground values, otherwise false .

$$\text{Rule } \frac{V == W}{\text{is-equal}(V : \text{ground-values}, W : \text{ground-values}) \rightsquigarrow \text{true}}$$

$$\text{Rule } \frac{V \neq W}{\text{is-equal}(V : \text{ground-values}, W : \text{ground-values}) \rightsquigarrow \text{false}}$$

$$\text{Rule } \text{is-equal}(V : \sim \text{ground-values}, W : \text{values}) \rightsquigarrow \text{false}$$

$$\text{Rule } \text{is-equal}(V : \text{values}, W : \sim \text{ground-values}) \rightsquigarrow \text{false}$$
